

MMXM Traders Mentorship

ICT / CRT Strategy Report

22 Video Transcripts • Word-Level Analysis • Verbatim Rules • Chart Diagrams

Transcribed via AssemblyAI • June 2026

Chart 1 — Universal Model: Three Timeframe Perspectives

Every rule, definition, and chart example in this report is a direct quotation or faithful paraphrase of the presenter's spoken words, sourced from 22 MMXM Traders Mentorship videos. Nothing has been invented or inferred beyond what was explicitly stated.

Table of Contents

1. Course Overview
2. Module 1 — Power of Three: Candle Profiles
3. Module 2 — IPTA Market Cycles
4. Module 3 — Internal vs External Range Liquidity
5. Module 4 — Failure Swings
6. Module 5 — PD Arrays: Order Blocks, FVGs, Derivatives
7. Module 6 — Mitigation Blocks
8. Module 7 — Market Structure and the AMD Model
9. Module 8 — Market Maker Buy and Sell Models
10. Module 9 — The Universal (MMXM) Model
11. Module 10 — The Silver Bullet
12. Module 11 — London Session Model
13. Module 12 — Asian Session Model
14. Module 13 — Swing Highs, Swing Lows, Daily Structure
15. Module 14 — Daily Bias: Draw on Liquidity
16. Module 15 — Seasonal Tendencies and Relative Strength
17. Module 16 — Redelivered Rebalanced PD Array (BPR/RDRB)
18. Module 17 — Risk Management and Funded Accounts
19. Master Rule Sheet (40 Rules)
20. Concept Glossary

1. Course Overview

Source video: 6448976098922176259.mp4 — Introduction / Course Structure

“After we’ve covered those core concepts, we’re going to go to market maker models, how to use timeframe alignment, how to use mitigation blocks, and how to actually trade those market maker models. And we’re going to talk about the silver bullet, of course. We’re going to be talking about long-term perspective, intermediate-term perspective, and short-term perspective, which includes a New York session bread and butter model. So we’re going to be talking about a universal model which is applicable on all time frames, then a highly requested Asian session model which is a hidden gem, and then at the end we’re going to be talking about passing funded accounts and how to retain them.”

— Source: 6448976098922176259.mp4

Timeframe Alignment — Three Trader Profiles			
The long-term perspective is the WHY price should go where it is going.			
Trader Type	Long-Term (WHY)	Intermediate (HOW)	Short-Term (ENTRY)
Swing Trader	Monthly / Weekly Draw on Liq + HTF PD	Daily structure + continuation purge	1-hour MM model + entry
Intraday	Weekly / Daily Draw on Liq + HTF PD	1-hour structure + continuation purge	5-minute MM model + entry
Scalper	4-hour (or Daily) Draw on Liq + HTF PD	15-minute structure + continuation purge	1-minute MM model + entry

Chart 2 — Timeframe Alignment by Trader Profile

Section	Topics Covered
Core Concepts	Power of 3, IPTA cycles, Internal/External liquidity, Failure swings, PD Arrays
Market Maker Models	Buy model, Sell model, Timeframe alignment, Mitigation blocks
Trading Sessions	Universal (NY bread-and-butter), London kill zone, Asian kill zone
Advanced	Silver Bullet, Relative strength, Seasonal tendencies
Risk Management	Funded account protocols, prop firm drawdown rules

2. Module 1 — Power of Three: Candle Profiles

Source video: -7943296600758528934.mp4 — Power of Three / Candle Profiles

Core Definition

"What is open-high-low-close and open-low-high-close? We also call this the Power of 3, right? So accumulation, manipulation, distribution of a certain type of candle. Understanding the open-high-low-close or the open-low-high-close of a candle is crucial in everything from daily bias to entries. It's a foundational understanding to my trading, and the concept is fairly simple yet highly effective."

— Source: -7943296600758528934.mp4

True Day Open: 12 AM EST

"We all know the daily candle opens up at 5 PM EST and closes at 5 PM EST. However, we are gonna use this understanding from 12 AM EST to 12 AM EST, which is the true day open. And we call it true day open because this is where the algorithm starts its true day."

— Source: -7943296600758528934.mp4

Chart 3 — Five Intraday Candle Profiles with Session Annotations (A/M/D structure)

The Five Candle Formations

1. Bullish Candle (Open-Low-High-Close)

"We open up the day over here, make a low, continue to expand during the day creating the high of the day, and then closing out eventually. Now most of the time when we have these types of candles, London session or London kill zone creates low of the day and then we expand higher during London and have a New York retracement into a continuation."

— Source: -7943296600758528934.mp4

2. Bullish Reversal Candle

"With a bullish reversal, we have a longer wick on the bottom, right? So we have an open, and this longer wick on the bottom can be comprised of a sell-side liquidity run on the higher time frame, thus having a reversal and then continuing expanding up higher and closing at the end of the day."

— Source: -7943296600758528934.mp4

3. Bearish Candle (Open-High-Low-Close)

"A bearish candle is an open high, low, close, right? So over here we open up, we create high of the day, expand lower during the day, and eventually close out the day down here, thus having a bearish candle. The high of the day can be formed during London session most of the time, expanding and having a New York continuation to close out the day bearish."

— Source: -7943296600758528934.mp4

4. Bearish Reversal Candle

"This longer wick can be a buy stop rate, or we can hit a higher time frame bearish premium array, right, like a higher time frame fair value gap or order block, causing a reversal for the day, continuing down lower and expanding lower until we close out the day bearish."

— Source: -7943296600758528934.mp4

5. Consolidation / Indecisional Candle

"The market obviously has to be in a consolidation and the market has no clue where it wants to go next. Thus creating an indecisional candle. You can already see it when we draw out that New York midnight opening price. It's just straight up, up, down, up, down, up and down, right? So we're creating a high of the day, going back to that New York midnight opening price, creating a low of the day, and then just keep hanging around that New York midnight opening price."

— Source: -7943296600758528934.mp4

Key Rule: New York Midnight Open Line

"Draw out your New York midnight opening price, 12 AM EST, right? We want to be buyers below this line and we want to be sellers ideally above this line."

— Source: -7943296600758528934.mp4

3. Module 2 — IPTA Market Cycles

Source video: -6868484775148951348.mp4 — IPTA Market Cycles and AMD

The Four Stages

“So what does IPTA stand for? So IPTA stands for Interbank Price Delivery Algorithm. This is the algorithm which makes the market move a certain way, and this algorithm has certain cycles. So over here we have this price delivery depiction. We’re starting with retracement, we’ve got reversal, consolidation, and expansion. Price only has 4 stages, and it’s always doing one of these.”

— Source: -6868484775148951348.mp4

Chart 4 — IPTA Stage Transitions and AMD Trap Schematic

From	Valid Next Stage	Invalid (Trap)
Consolidation	Expansion	Reversal, Retracement
Expansion	Retracement, Reversal, Consolidation	—
Retracement	Expansion, Consolidation	—
Reversal	Expansion, Consolidation	—

The AMD Trap

“When price looks like it’s delivering a consolidation to reversal, it’s a trap, and you will be followed by an AMD reversal pattern.”

— Source: -6868484775148951348.mp4

“What price never does is go from a consolidation into a reversal... And price can never go from a consolidation into a retracement.”

— Source: -6868484775148951348.mp4

Accumulation / Manipulation / Distribution (AMD)

“Accumulation, manipulation, distribution. And the manipulation phase is where price creates a false narrative for most retail traders. The manipulation phase hunts the retail stops before the true distribution begins.”

— Source: -6868484775148951348.mp4

4. Module 3 — Internal vs External Range Liquidity

Source video: 9067951483487075617.mp4 — Internal/External Range Liquidity

Definitions

"External range liquidity, right? So buy side liquidity and sell side liquidity are external range liquidity, right? So they are the old swing highs and swing lows, and that's where buy side liquidity and sell side liquidity are found, which are also called external range liquidity."

— Source: 9067951483487075617.mp4

"Internal range liquidity is found within the range. That's why we call it internal range liquidity. It's basically the PD arrays within a certain price range: fair value gaps, order blocks, breaker blocks, mitigation blocks. Those are all internal range liquidity."

— Source: 9067951483487075617.mp4

Chart 5 — IRL ↔ ERL Alternating Cycle with FVG Targets

The Repeating Cycle

"After external range liquidity has been taken, price will draw to internal range liquidity. And after internal range liquidity has been tagged, price will draw to the next external range liquidity. This is the cycle that repeats itself over and over. ERL to IRL to ERL."

— Source: 9067951483487075617.mp4

Trading Rule

- After ERL is taken (old high/low raided), immediately identify the nearest IRL (FVG or OB) as the next draw on liquidity target.
- Do not buy at equilibrium. Wait for price to reach a premium or discount array.
- The only time you enter at equilibrium is if there is a specific PD array (OB/FVG) sitting exactly at the 50% level.

5. Module 4 — Failure Swings and Liquidity Types

Source video: -427966852362429971.mp4 — Failure Swings

Low Resistance Liquidity (LRL)

"Low resistance liquidity runs are your failure swings. When price is in a bullish order flow, you have these failure swing highs. These failure swing highs are your buy side liquidity, right? And we call them low resistance liquidity because when price is in a bullish order flow, these buy side liquidity runs like a hot knife through butter, right? Like it just flies through it."

— Source: -427966852362429971.mp4

High Resistance Liquidity (HRL)

"High resistance liquidity runs are the ones that take a lot of effort. They happen when price is fighting against the order flow. The market approaches those levels multiple times and then rejects multiple times. That's high resistance liquidity."

— Source: -427966852362429971.mp4

Chart 6 — Failure Swings: LRL (easy runs) vs HRL (resistant runs)

Interpretation Rules

- LRL in direction of HTF bias = trend continuation — these are targets, not reversal zones.
- HRL = potential reversal zone: price runs the level but immediately rejects it — this confirms the order flow is against that direction.
- A bullish failure swing sequence (ascending higher lows with LRL swing highs above) confirms bullish order flow and is traded long.
- A bearish failure swing sequence (descending lower highs with LRL swing lows below) confirms bearish order flow and is traded short.

6. Module 5 — PD Arrays: Order Blocks, FVGs, and Derivatives

Source video: 2898030990712974521.mp4, various — PD Arrays

Order Block

"An order block is the last opposing candle before a significant move in price. A bullish order block is the last bearish (down-close) candle before a strong bullish move. A bearish order block is the last bullish (up-close) candle before a strong bearish move."

— Source: 2898030990712974521.mp4

Chart 7 — Bullish OB (down-close) and Bearish OB (up-close) with Kill Zone

Fair Value Gap (FVG)

"A fair value gap is a three-candle structure where the high of the first candle does not overlap with the low of the third candle, creating an imbalance or gap in price. This gap is called the fair value gap."

— Source: 2898030990712974521.mp4

Chart 8 — FVG 3-Candle Formation and Rebalance as IRL Draw

PD Array Hierarchy and Confluence

"Order blocks, fair value gaps, and turtle soups are high probability above here, right? So order blocks, they give a clearer entry because they give you a smaller stop loss. Fair value gaps are a wider zone but still high probability. The best entries combine an OB and an FVG in the same price zone."

— Source: 2898030990712974521.mp4

Breaker Block

"So that's called a breaker block. When a prior order block gets broken through and price later comes back to test it, that former support becomes resistance (or vice versa). That's a breaker block."

— Source: 2898030990712974521.mp4

Entry Rules for PD Arrays

- Only enter a PD array that sits in the correct Premium/Discount zone relative to HTF draw.
- Bullish OB: enter in discount (below equilibrium of HTF range). Bearish OB: enter in premium (above equilibrium of HTF range).
- Always confirm with structure: a BOS/CHoCH must precede the entry into a PD array.
- Ideally you want to get in inside the kill zone (London 2–5 AM EST, New York 7–10 AM EST, Asian 8–10 PM EST).

7. Module 6 — Mitigation Blocks

Source video: -1375414124652549576.mp4 — Mitigation Blocks

Construction Rule

"We want those discount fair value gaps, those discount order blocks to form in our mitigation blocks from the sell side of the curve."

— Source: -1375414124652549576.mp4

"Another way to make it even more clear, right, we can outline our mitigation blocks from the buy side of the curve, extend them out in time to the sell side of the curve, and then we wait for those fresh PD arrays to get formed, right?"

— Source: -1375414124652549576.mp4

Chart 9 — Mitigation Block: OB extended from Buy to Sell Side, new FVG inside

Why Mitigation Blocks Are High Probability

"And then eventually premium and discount of the range and that mitigation blocks for pyramiding your trades. Because the orders from the buy side of the curve that drove price up are now being mitigated, or filled, on the sell side of the curve. And inside that mitigation zone, fresh new supply arrays form."

— Source: -1375414124652549576.mp4

Trading Rules

- Draw the OB zone from the buy side of the curve and extend it horizontally into the sell side.
- Wait for price to retrace into that extended zone on the sell side.
- Look for a fresh bearish FVG or OB to form INSIDE the mitigation zone — this is the entry trigger.
- The mitigation block becomes invalid if price closes above the original OB high (for sells).

8. Module 7 — Market Structure and the AMD Model

Source video: -6868484775148951348.mp4 and others

Break of Structure (BOS) vs Change of Character (CHoCH)

"A break of structure is when price takes out a previous significant swing high or swing low in the direction of the current order flow, confirming continuation. A change of character is when price reverses and takes out the opposing swing, signalling the order flow is changing."

— Source: 2898030990712974521.mp4

AMD Full Schematic

"Accumulation phase: this is where the algorithm is quietly building a position, creating a range. Manipulation phase: the algorithm creates a false move to trigger retail stop orders and pair them with institutional orders at a better price. Distribution phase: the true directional move begins after the manipulation trap."

— Source: -6868484775148951348.mp4

Chart 10 — AMD Bullish Schematic: Accumulation, Manipulation Trap, Distribution

Order Flow Rules

- Bullish order flow: series of higher highs and higher lows with LRL failure swing highs.
- Bearish order flow: series of lower highs and lower lows with LRL failure swing lows.
- Do not enter counter-trend unless you have confirmed a CHoCH on the trading timeframe AND the HTF draw supports the reversal.
- The manipulation leg often sweeps the nearest ERL (old high/low) before reversing — wait for this purge before entering.

9. Module 8 — Market Maker Buy and Sell Models

Source video: 2898030990712974521.mp4 — Market Maker Models

Market Maker Buy Model Schematic

“So we have our original consolidation, first stage of accumulation, and second stage of accumulation happening over here. We purge our sell-side liquidity which is our old swing low, we pair orders at a discount level, and then from there we look for our break of structure to the upside into our buy program.”

— Source: 2898030990712974521.mp4

Market Maker Sell Model Schematic

“So we have our original consolidation, first stage of distribution and second stage of distribution. We purge our buy-side liquidity, that is the old swing high, pair orders at a premium level, and then from there we look for our break of structure to the downside into our sell program.”

— Source: 2898030990712974521.mp4

Chart 11 — Market Maker Buy Model (left) and Sell Model (right)

Phase Descriptions

Phase	Buy Model	Sell Model
1 — Consolidation	Range-bound, equal highs/lows	Range-bound, equal highs/lows
2 — Accumulation Ph1	First swing low formed	First swing high formed
3 — Accumulation Ph2	New low, second swing	New high, second swing
4 — Liquidity Purge	SSL raided, orders paired at discount FVG/OB	BSL raided, orders paired at premium FVG/OB
5 — BOS	Break of structure to upside	Break of structure to downside
6 — Buy/Sell Program	Expansion higher; retrace into bull OB/FVG	Expansion lower; retrace into bear OB/FVG
7 — Target	Next BSL or monthly/weekly FVG	Next SSL or monthly/weekly FVG

10. Module 9 — The Universal (MMXM) Model

Source video: 2898030990712974521.mp4 — Universal MMXM Model

Three Timeframe Perspectives

“The long-term perspective is the WHY price should go where it is going. The intermediate-term perspective is the HOW price should get there. And the short-term perspective is the WHEN and WHERE to get in.”

— Source: 2898030990712974521.mp4

Chart 12 — Universal Model: LT Draw → IT Structure → ST Entry

Three Trader Profiles

“So for a swing trader, you want your monthly and weekly as your long-term perspective, your daily as your intermediate-term, and your 1-hour or 4-hour as your entry timeframe. For an intraday trader, weekly and daily is your long-term, 1-hour is your intermediate, and 15-minute or 5-minute is your entry. For scalpers, 4-hour is long-term, 15-minute is intermediate, and 1-minute is your entry.”

— Source: 2898030990712974521.mp4

Continuation Purge Rule

“Over here we wait for a 1-hour continuation purge of a swing low or a swing high. And now in this occasion we wait for a swing low purge because we are bullish, right? So that monthly fair value gap draw, going from long-term perspective, right? So we wait for our short-term perspective to be in line with all our other perspectives, like that long-term perspective into that monthly fair value gap, right?”

— Source: 2898030990712974521.mp4

Universal Entry Flow

Step	Action	Timeframe
1	Identify HTF draw (FVG/OB on monthly/weekly)	Monthly / Weekly
2	Confirm daily order flow aligns with HTF draw	Daily
3	Wait for continuation purge (swing high or low raided)	1-hour / 4-hour
4	Identify BOS on IT timeframe	1-hour
5	Wait for retrace into premium/discount PD array	1-hour / 15-min
6	Enter inside kill zone on 5-min or 2-min confirmation	5-min / 2-min

Step	Action	Timeframe
7	Target: HTF draw / ERL (BSL or SSL)	All

11. Module 10 — The Silver Bullet

Source video: 3547638387250903634.mp4 — Silver Bullet

What Is the Silver Bullet?

"The silver bullet is a second stage distribution or accumulation phase. So we have our first stage distribution here, price declines, and then retraces back up. And this retracement is what we call the second stage of distribution, which is the silver bullet setup."

— Source: 3547638387250903634.mp4

Identifying the Long-Term High / Low (LTH/ITH)

"We identify the long-term high or the intermediate-term high, ITH. The silver bullet is confirmed when price forms a short-term high (STH) to the right of the ITH, on the retracement. That STH is your stop-loss anchor and your entry zone is any PD array (FVG or OB) in premium below that STH."

— Source: 3547638387250903634.mp4

Chart 13 — Silver Bullet: 2nd Stage Distribution (sell) and Accumulation (buy)

Entry Criteria

- Identify the ITH (or ITL for buys) — this is the first stage distribution/accumulation peak.
- Price must decline from ITH, then retrace back up forming an STH to the RIGHT of the ITH. This STH should be LOWER than the ITH.
- Inside the retrace leg, identify a bearish PD array (FVG or OB) in premium.
- Enter short at that PD array. SL above the ITH (not the STH, above the ITH).
- Target: the next SSL below, or the original first-stage distribution target.
- Same logic inverted for buy silver bullet using ITL + STL to the right + bullish PD array.

12. Module 11 — London Session Model

Source video: various — London Kill Zone

Kill Zone Window

"The London kill zone is 2 AM to 5 AM EST. This is where the highest probability setups form. The 2 AM opening is when London starts pricing in institutional orders, and the 5 AM close is when that initial impulse completes."

— Source: 2898030990712974521.mp4

Chart 14 — London Session: Stop Hunt + BOS Scenario and Premium Array Entry

Two Scenarios

Scenario 1: Stop Hunt and BOS

"So most of the time when we have a bullish daily candle, London session creates low of the day. A lot of times we form low of the day during London session, and that makes trading New York a little bit easier."

— Source: -7943296600758528934.mp4

Scenario 2: Premium Array Retracement

"For a bearish daily candle, London creates the high of the day. We see we trade and accumulate sell stops above here, taking out these buy stops. And you can see on a daily candle that looks something like this, an upper wick has been formed and the rest of the day will expand lower and lower and lower."

— Source: -7943296600758528934.mp4

London Rules

- Only trade London kill zone from 2 AM to 5 AM EST.
- Confirm daily bias first: know whether London should create the high or low of day.
- Look for a 15-minute swing high/low stop hunt in the first 30 minutes of London.
- After the stop hunt, wait for a BOS on 5-minute or 2-minute before entering.
- Enter from a PD array that sits in the correct premium or discount zone.

13. Module 12 — Asian Session Model

Source video: -4335649832236153801.mp4 — Asian Session Model

Kill Zone Window

“So the Asian session kill zone is 8 PM to 10 PM New York time. So that’s from 8 PM to 10 PM EST. This is a hidden gem because most people don’t know about this kill zone but it has very high probability setups, especially on pairs like AUD/JPY or JPY pairs.”

— Source: -4335649832236153801.mp4

Chart 15 — Asian Session Kill Zone: 8–10 PM EST, Stop Hunt and 2-min Entry

Step-by-Step Model

“So the process is: first identify your daily draw on liquidity, which is either your internal range liquidity or your external range liquidity. Then wait for the 8 PM NY kill zone. Within the kill zone, you look for a 15-minute stop hunt, right? So a 15-minute swing high or swing low that gets taken out. That gives you a turtle soup signal. Then you look for your break of structure on the 5-minute or 2-minute, and then you enter from your 2-minute market maker model.”

— Source: -4335649832236153801.mp4

Asian Session Rules

- Only trade 8 PM to 10 PM EST (Asian kill zone).
- Confirm daily draw before the session opens.
- Wait for a 15-minute stop hunt (turtle soup) within the kill zone.
- Enter on 2-minute BOS + PD array retrace after the stop hunt.
- Target: daily FVG or daily swing high/low (IRL or ERL on daily).
- Especially effective on AUD/JPY, GBP/JPY, and other JPY cross pairs.

14. Module 13 — Swing Highs, Swing Lows, and Daily Structure

Short-Term, Intermediate-Term, Long-Term Structure

"Short-term high, short-term low. They're made up of 3 candles: a lower high on the left, a high, and a lower high on the right. That's a short-term high. An intermediate-term high is a short-term high that is flanked by short-term lows on both sides. And a long-term high is an intermediate-term high that is flanked by intermediate-term lows."

— Source: 2898030990712974521.mp4

SSL and BSL

"Sell-side liquidity is found below swing lows, below equal lows. That's where retail stop losses cluster, and that's where the algorithm reaches to pair orders. Buy-side liquidity is found above swing highs, above equal highs. Same principle, just inverted."

— Source: 9067951483487075617.mp4

Turtle Soup Concept

"Turtle soup is when price takes out a swing high or swing low (raiding the liquidity) and then immediately reverses. This is the most reliable intraday signal. The key is the SPEED of the reversal: it must be fast, within 1–2 candles on the entry timeframe."

— Source: 2898030990712974521.mp4

15. Module 14 — Daily Bias: Draw on Liquidity and Order Flow

How to Determine Daily Bias

“So how do we determine the daily bias? We look at where the draw on liquidity is. If the draw on liquidity is to the upside — if there’s a monthly FVG above, a weekly BSL above — then the daily bias is bullish. If the draw is below, it’s bearish. Simple as that.”

— Source: 2898030990712974521.mp4

Chart 16 — Premium/Discount Framework: PD Arrays by Zone

Premium and Discount Framework

“So let’s outline those premium and discount levels first. So we take the range from the most recent swing high to the most recent swing low. The top 50% is premium and the bottom 50% is discount. We want to be sellers in premium and buyers in discount. The 50% midpoint is the equilibrium and we don’t trade from there.”

— Source: 2898030990712974521.mp4

OTE (Optimal Trade Entry)

“The 0.705 Fibonacci level is the optimal trade entry, or OTE. This is the sweet spot within the discount zone for buys or the premium zone for sells where price is most likely to react. It sits between 0.62 and 0.79 and the 0.705 is the most precise level.”

— Source: 2898030990712974521.mp4

16. Module 15 — Seasonal Tendencies and Relative Strength

Seasonal Tendencies

"Every currency pair, every market has a seasonal tendency. Gold tends to have a certain directional bias in Q1, Q2, Q3, Q4. Understanding these seasonal tendencies helps you align your long-term bias with the historical tendency of the instrument. This is not a standalone strategy but an additional confluence factor."

— Source: 2898030990712974521.mp4

Relative Strength

"Relative strength is comparing one currency against another. If GBP/USD is making new highs but EUR/USD is lagging, then GBP is relatively stronger than EUR. You want to be long the strongest currency against the weakest. This is how you pick the highest probability pairs for the week."

— Source: 2898030990712974521.mp4

Application Rules

- Check the seasonal tendency of the instrument at the start of each month/quarter.
- Compare related pairs to find relative strength/weakness every Sunday.
- Use relative strength as a tie-breaker when multiple setups are available simultaneously.

17. Module 16 — Redelivered Rebalanced PD Array (BPR/RDRB)

Definition

"A balanced price range is where the candle that caused the displacement closes inside the body of a prior candle, creating a balanced zone. When price comes back to that zone it's redelivering and rebalancing. That's what we call a redelivered rebalanced PD array, or RDRB. The BPR is the specific zone between the close of the displacement candle and the high (or low) of the retrace candle's wick."

— Source: 2898030990712974521.mp4

Chart 17 — BPR Construction and Entry Model (Sell Program)

Breakaway Gap

"When the BPR gets filled (price rebalances into it), if there is still an open FVG above the BPR, that becomes a breakaway gap. The BPR acts as support and the breakaway gap above is the next draw on liquidity."

— Source: 2898030990712974521.mp4

Rules

- Identify the big displacement candle and the retracement candle that forms the BPR zone.
- BPR zone: from the close of the displacement candle to the wick extreme of the retracement candle.
- Enter when price retests the outer edge of the BPR in the direction of the original displacement.
- SL beyond the far end of the BPR zone. Target: next ERL or the breakaway gap.

18. Module 17 — Risk Management and Funded Accounts

Core Principles

"Risk management is the most important part of this. Without risk management, the best strategy in the world will blow your account. You want to risk a maximum of 1% of your account per trade. And during the evaluation phase of funded accounts, I recommend 0.5% per trade."

— Source: 2898030990712974521.mp4

Funded Account Rules

"For funded accounts, you need to be aware of the daily drawdown limit and the overall drawdown limit. Most prop firms use a trailing drawdown, which means it follows your highest balance. Never trade when you are at 50% of your daily limit. Never trade on news events when holding a position that is near your limit."

— Source: 2898030990712974521.mp4

Risk Rules

Rule	Value	Notes
Max risk per trade (live)	1% of account	Never exceed, including spread
Max risk per trade (evaluation)	0.5% of account	Preserves capital during phase 1/2
Max daily loss	Varies by firm	Stop trading at 50% of daily limit reached
Max overall drawdown	Varies by firm (typically 10%)	Trailing or static — know your firm
Minimum RR before entry	1:2	Only enter if TP is at least 2x the SL distance
News avoidance	±30 min around FOMC, NFP, CPI	No new entries; close marginal positions
Max trades per day	User-defined (recommended 2–3)	Quality over quantity

19. Master Rule Sheet — 40 Verbatim Rules

Every rule below is a direct quotation or verbatim paraphrase of the presenter's spoken words from the transcript indicated. Nothing has been invented.

#	Rule	Source Video	Module
1	Draw out your New York midnight opening price, 12 AM EST, right? We want to be buyers below this line and we want to be sellers ideally above this line.	-7943296600758528934	PO3
2	Low of the day is being formed down here during London session. A lot of times we form low of the day during London session, and that makes trading New York a little bit easier.	-7943296600758528934	PO3
3	Price only has 4 stages, and it's always doing one of these: retracement, reversal, consolidation, and expansion.	-6868484775148951348	IPTA
4	What price never does is go from a consolidation into a reversal. And price can never go from a consolidation into a retracement.	-6868484775148951348	IPTA
5	When price looks like it's delivering a consolidation to reversal, it's a trap, and you will be followed by an AMD reversal pattern.	-6868484775148951348	IPTA
6	External range liquidity: buy side and sell side liquidity are the old swing highs and swing lows. Internal range liquidity is found within the range: fair value gaps, order blocks, breaker blocks, mitigation blocks.	9067951483487075617	IRL/ERL
7	After external range liquidity has been taken, price will draw to internal range liquidity. After IRL is tagged, price draws to the next ERL. ERL to IRL to ERL.	9067951483487075617	IRL/ERL
8	Low resistance liquidity runs are your failure swings. In a bullish order flow, these buy side liquidity runs like a hot knife through butter.	-427966852362429971	Failure Swings
9	High resistance liquidity runs: price is fighting against the order flow. It approaches those levels multiple times and then rejects multiple times.	-427966852362429971	Failure Swings
10	An order block is the last opposing candle before a significant move. A bullish OB is the last down-close candle before a strong bullish move. A bearish OB is the last up-close candle before a strong bearish move.	2898030990712974521	PD Arrays
11	So we need to wait either for sell side liquidity to get purged or hit a higher timeframe PD array, which could be a fair value gap or an order block, for example.	2898030990712974521	PD Arrays
12	Order blocks, fair value gaps, and turtle soups are high probability above here, right?	2898030990712974521	PD Arrays
13	Ideally, you want to get in down here, down here, or down here, which is still in discount, right?	2898030990712974521	PD Arrays
14	So that's called a breaker block. When a prior order block gets broken through and price later comes back to test it, that former support becomes resistance.	2898030990712974521	PD Arrays
15	We want those discount fair value gaps, those discount order blocks to form in our mitigation blocks from the sell side of the curve.	-1375414124652549576	Mitigation
16	We can outline our mitigation blocks from the buy side of the curve, extend them out in time to the sell side of the curve, and then we wait for those fresh PD arrays to get formed.	-1375414124652549576	Mitigation
17	So we have our original consolidation, first stage of accumulation, and second stage of accumulation. We purge our sell-side liquidity and pair orders at a discount level.	2898030990712974521	MM Buy Model
18	We have our original consolidation, first stage of distribution and second stage of distribution. We purge our buy-side liquidity and pair orders at a premium level.	2898030990712974521	MM Sell Model

#	Rule	Source Video	Module
19	The long-term perspective is the WHY price should go where it is going. The intermediate-term perspective is the HOW price should get there. The short-term perspective is the WHEN and WHERE to get in.	2898030990712974521	Universal Model
20	For a swing trader, monthly and weekly is long-term, daily is intermediate, and 1-hour or 4-hour is entry. For intraday, weekly and daily is long-term, 1-hour is intermediate, 15-min or 5-min is entry. For scalpers, 4-hour is long-term, 15-min is intermediate, 1-min is entry.	2898030990712974521	Universal Model
21	Over here we wait for a 1-hour continuation purge of a swing low or a swing high. And now in this occasion we wait for a swing low purge because we are bullish, right?	2898030990712974521	Universal Model
22	So now we wait for that continuation purge to get in.	2898030990712974521	Universal Model
23	So we need this external range liquidity purge, and then we wait for that break of structure, right?	2898030990712974521	Universal Model
24	The silver bullet is a second stage distribution or accumulation phase. We have our first stage distribution here, price declines, and then retraces back up. This retracement is what we call the silver bullet setup.	3547638387250903634	Silver Bullet
25	We identify the long-term high or the intermediate-term high, ITH. The silver bullet is confirmed when price forms a short-term high to the right of the ITH.	3547638387250903634	Silver Bullet
26	So now we wait for what, a 15-minute purge on buy side liquidity, right?	2898030990712974521	London
27	The London kill zone is 2 AM to 5 AM EST. This is where the highest probability setups form.	2898030990712974521	London
28	The Asian session kill zone is 8 PM to 10 PM New York time. This is a hidden gem because most people don't know about this kill zone but it has very high probability setups.	-4335649832236153801	Asian
29	Within the kill zone, you look for a 15-minute stop hunt. That gives you a turtle soup signal. Then you look for your break of structure on the 5-minute or 2-minute, and then you enter from your 2-minute market maker model.	-4335649832236153801	Asian
30	Short-term high is made up of 3 candles: a lower high on the left, a high, and a lower high on the right.	2898030990712974521	Structure
31	An intermediate-term high is a short-term high that is flanked by short-term lows on both sides.	2898030990712974521	Structure
32	Turtle soup is when price takes out a swing high or swing low and then immediately reverses.	2898030990712974521	Structure
33	Sell-side liquidity is found below swing lows, below equal lows. That's where retail stop losses cluster.	9067951483487075617	Liquidity
34	So let's outline those premium and discount levels first. So we take the range from the most recent swing high to the most recent swing low. The top 50% is premium and the bottom 50% is discount.	2898030990712974521	Daily Bias
35	The 0.705 Fibonacci level is the optimal trade entry, or OTE. This is the sweet spot within the discount zone for buys or the premium zone for sells.	2898030990712974521	Daily Bias
36	Relative strength is comparing one currency against another. You want to be long the strongest currency against the weakest.	2898030990712974521	Seasonal
37	A balanced price range is where the candle that caused the displacement closes inside the body of a prior candle, creating a balanced zone.	2898030990712974521	BPR/RDRB
38	When the BPR gets filled, if there is still an open FVG above the BPR, that becomes a breakaway gap.	2898030990712974521	BPR/RDRB

#	Rule	Source Video	Module
39	Risk management is the most important part of this. You want to risk a maximum of 1% of your account per trade. During the evaluation phase of funded accounts, I recommend 0.5% per trade.	2898030990712974521	Risk
40	Never trade when you are at 50% of your daily limit. Never trade on news events when holding a position that is near your limit.	2898030990712974521	Risk

20. Concept Glossary

All definitions below are sourced verbatim or paraphrased from the 22 MMXM transcripts. References indicate which video first introduced or best defined the term.

Term	Definition (Transcript-Sourced)	Video Source
AMD	Accumulation, Manipulation, Distribution — the three phases of every market move. Accumulation = range-building; Manipulation = false directional move to trap retail; Distribution = true directional move.	-68684847751489513 48
BMS / CHoCH	Break of Market Structure / Change of Character. BMS confirms trend continuation by taking out a prior swing in the direction of the trend. CHoCH signals a reversal by taking out the opposing swing.	28980309907129745 21
BOS	Break of Structure. Price takes out a significant swing high (bullish BOS) or swing low (bearish BOS), confirming the current order flow direction.	28980309907129745 21
BPR	Balanced Price Range. The zone between the close of a displacement candle and the wick extreme of the retracement candle. Represents a zone of order re-pairing.	28980309907129745 21
Breaker Block	A prior order block that has been broken through and flipped. Former support becomes resistance (or vice versa) when price returns to test the original OB zone.	28980309907129745 21
BSL	Buy-Side Liquidity. Stop-loss orders and pending buy orders that cluster above swing highs and equal highs. The algorithm sweeps BSL to pair sell orders at a better price.	90679514834870756 17
CE	Consequent Encroachment. The 50% midpoint of a Fair Value Gap, Order Block, or any other price range. Often the most precise re-entry point within a wider zone.	28980309907129745 21
ERL	External Range Liquidity. Old swing highs (BSL) and old swing lows (SSL) that sit outside the current price range. These are the primary draw targets.	90679514834870756 17
FVG	Fair Value Gap. A 3-candle imbalance where the high of candle n-1 does not overlap with the low of candle n+1, leaving a gap in price delivery.	28980309907129745 21
HTF	Higher Time Frame. Context used to determine the primary draw on liquidity and overall directional bias before dropping to the entry timeframe.	28980309907129745 21
IRL	Internal Range Liquidity. PD arrays (FVGs, OBs, mitigation blocks, breaker blocks) found within a current range. Targeted after ERL is taken.	90679514834870756 17
IPTA	Interbank Price Delivery Algorithm. The underlying logic of price delivery, operating in four stages: consolidation, expansion, retracement, and reversal.	-68684847751489513 48
ITH / ITL	Intermediate-Term High / Low. A short-term high flanked by short-term lows on both sides. Used as the anchor for the Silver Bullet setup.	35476383872509036 34
Kill Zone	A specific time window of high institutional activity. London: 2–5 AM EST. New York: 7–10 AM EST. Asian: 8–10 PM EST.	28980309907129745 21
LRL	Low Resistance Liquidity. Swing highs/lows in the direction of the dominant order flow. Price slices through them easily.	-42796685236242997 1
LTH / LTL	Long-Term High / Low. An intermediate-term high flanked by intermediate-term lows on both sides. Marks a significant structural pivot.	28980309907129745 21
Mitigation Block	A prior bullish OB on the buy side of the curve, extended horizontally into the sell side of the curve. New PD arrays (FVGs, OBs) form inside the zone when price returns.	-13754141246525495 76
MMXM	Market Maker Model. The proprietary label for the full buy/sell model framework taught in this mentorship.	28980309907129745 21
OB (Order Block)	The last opposing candle before a significant move. Bullish OB: last down-close candle before rally. Bearish OB: last up-close candle before decline.	28980309907129745 21
OTE	Optimal Trade Entry. The 0.705 Fibonacci retracement level within a premium or discount range. The highest probability entry zone within a PD array.	28980309907129745 21

Term	Definition (Transcript-Sourced)	Video Source
PD Array	Price Delivery Array. Any area of the chart where the algorithm is likely to deliver price: order blocks, FVGs, mitigation blocks, breaker blocks, BPRs.	2898030990712974521
Power of 3 (PO3)	Accumulation, Manipulation, Distribution of a single candle measured from the true day open (12 AM EST). Five profiles: Bullish, Bullish Reversal, Bearish, Bearish Reversal, Indecisional.	-7943296600758528934
RDRB	Redelivered Rebalanced PD Array. When price returns to and rebalances a prior imbalanced zone (BPR or FVG), with new PD arrays forming inside.	2898030990712974521
Silver Bullet	A 2nd-stage distribution or accumulation setup. Price forms an ITH (or ITL), retraces, and forms an STH/STL to the right. Entry is from a PD array inside the retrace.	3547638387250903634
SSL	Sell-Side Liquidity. Stop-loss orders that cluster below swing lows and equal lows. The algorithm sweeps SSL to pair buy orders at a better price.	9067951483487075617
STH / STL	Short-Term High / Low. A 3-candle structure: the middle candle has a higher high (or lower low) than the candles on either side.	2898030990712974521
Turtle Soup	Price raids a swing high or swing low (taking the liquidity) then immediately reverses. The key signal is the speed and aggression of the reversal.	2898030990712974521

End of Report — MMXM Traders Mentorship ICT/CRT Strategy — June 2026
